

# HISTORIC DISTRIBUTION AND ABUNDANCE OF BISON IN THE ROCKY MOUNTAINS OF THE UNITED STATES

James A. Bailey, 581 Antelope Ridge Rd., Belgrade, MT, 59714

## ABSTRACT

Scant public awareness of the early distribution and abundance of bison (*Bison bison*) in the Rocky Mountains of the United States inhibits discussion of possible restoration of wild bison. A review of written evidence, largely from 1805-1845, indicates bison were widely distributed in intermountain valleys, with a major regional concentration spanning parts of Idaho, Montana and Wyoming. However, several interacting factors caused large spatial and temporal variation in bison abundance. Native American predation was likely a major influence on bison distribution and abundance during and shortly before 1805-1845. The area where bison were observed by early explorers underestimates the area where restoring productive herds of wild bison is possible.

Key words: Bison, *Bison bison*, Rocky Mountains, Historic Distribution

## INTRODUCTION

Although bison (*Bison bison*) are abundantly widespread as private livestock, there are proposals to reestablish wild herds that will be influenced by a preponderance of natural selection in diverse habitats (Gates et al. 2010, Bailey 2013). Developing a constituency for restoring wild bison requires broader awareness of former bison distribution, particularly in the Rocky Mountains.

Previous summaries of early bison distribution in the Rocky Mountains are from Allen (1877), Hornaday (1889) and Roe (1951). Meaney and Van Vuren (1993) compiled a list of early bison observations and of collected bison specimens for the Rocky Mountains of Colorado. For the northwest United States, reviews of bison in late-prehistoric to early historic time are in Kingston (1932), Butler (1978), Daubenmire (1985), Van Vuren and Bray (1985), Van Vuren (1987), Van Vuren and Dietz (1993), Lyman (2004), Williams (2005) and Grayson (2006). However, most of these references focus on bison west of the Rocky Mountains in southwest Idaho, eastern Washington and Oregon and the Great Basin.

Early literature based largely on 2nd hand descriptions, suggested that a unique strain of mountain bison once occupied the Rocky Mountains (Allen, 1877:447-448;

Hornaday, 1889:407-412; Roe, 1951:33-56; Meagher, 1973:14-17). Described characteristics of “mountain bison” may have been phenotypic with little or no genetics distinct from sympatric bison on the Great Plains. However, unique bison characteristics elicited by distinct environmental conditions in the Rocky Mountains constitute an ecotype, a portion of biodiversity without which the full expression of the *Bison bison* genotype would not occur.

## LITERATURE REVIEW

For the “Rocky Mountains” I included parts of Idaho, Montana, Wyoming, Colorado and northeast Utah. To emphasize continuous mountain habitat, I excluded island mountains in the plains of eastern Montana and the Bighorn Mountains of Wyoming. I did not include the Colorado Plateau of southwest Colorado and Utah.

I searched reports of fur trappers, trapping brigade leaders, missionaries, military expeditions and other explorers, largely from 1805-1845. Sources are the most accessible literature and are mostly edited versions of original writings. I noted the year, month and general location (usually a major river drainage) of bison observations (Tables 1-5). I omitted sightings with unclear locations. However, a few locations

were inferred from clearly described travel routes. Nothing can be inferred from diary entries lacking references to bison. Clearly, where bison were everyday abundant, writers often failed to record them. Records are organized by state and county to be most useful for today's readers.

Meaney and Van Vuren (1993) plotted locations of about 89 specimens (mostly skulls) and about 36 early recorded observations of bison in the Rocky Mountains of Colorado. Almost all these records are in northwest, north-central and central Colorado. I report additional records for Colorado and repeat observations, not specimens, from Meaney and Van Vuren.

## FINDINGS

Bison were found throughout the Rocky Mountains, except in the northern, more forested, mountains of Idaho and northwest Montana (Fig. 1, Tables 1-5). It is widely known, but misleading, that Meriwether Lewis and William Clark saw no bison in the mountains in 1805-06. In contrast, they noted old bison sign on the Jefferson River, in the Big Hole and Gallatin Valleys and on Bozeman pass, all in Montana. In 1806, Sacajawea said to Clark that her nation, the Shoshones, had "gathered cows" in the Big Hole Valley not many years before and that bison had recently been numerous in the Jefferson and Gallatin Valleys (Table 2).

There was a major abundance of bison in the central Rocky Mountains of the United States (Fig. 1). This area - broadly straddling the continental divide - encompasses parts of southwest Montana, east-central and southeast Idaho and southwest Wyoming, including the upper valleys of the Jefferson-Beaverhead, Salmon, Snake, Bear and Green rivers and their numerous tributaries. Fremont (1845:144) reported "mountain man" Tom Fitzpatrick's description of "immense numbers" of bison over this country "in about 1824". Numerous, mostly later, reports confirm Fitzpatrick's description (Tables 1-3).

Bison were observed in the Rocky Mountains during every month. A

preponderance of summer observations, especially in Wyoming and Idaho, reflects observations of seasonal cross-country travelers on the Oregon and Overland Trails. Most winter observations were in Idaho and Montana, also reflecting the distribution of observers. Mountain men favored wintering not far north of Fort Hall, Idaho where trapping brigades and Native Americans, often wintered on both sides of the Idaho/Montana border in part because bison were abundant in this area (Lewis and Phillips, 1923:114-119, 123, 130; Haines, 1965:108-109; Ferris, Ch. XXII, XXIII). These records provide very little information on habitat selection by bison in the mountains, or about elevational migrations.

Rocky Mountain bison were quite mobile and could be absent from large portions of the area at any time. Roe (1951:261-266) discussed locally inconsistent observations of bison abundance. For example, bison were reported as abundant in the Jefferson-Beaverhead Valleys, Montana, in the 1830s, where Lewis and Clark saw no bison in 1805-06, although Sacajawea said bison were once numerous there (Table 2). In 1812, Stuart found no bison in southeast Idaho where bison were plentiful in the 1820s and 1830s (Table 1). Stuart (Spaulding 1953) found few bison in the upper Green River valley of Wyoming where Hunt (Irving 1836) had observed many herds during the same season of the previous year (1811). In the 1830s, even more bison were recorded in this area (Table 3). Stuart had observed large, recently used Native American camps and trails and bones from recent abundant bison kills. At least three nations had recently hunted in the Wyoming area.

Mass movements of bison, sometimes over long distances, were reported by several diarists as responses to attacks by hunters. Many records of Euro-American brigades and accounts of Native American hunting parties describe cautions taken not to disturb bison, lest they leave an area, before an entire hunting party was brought up and prepared to kill a sufficient number of animals.

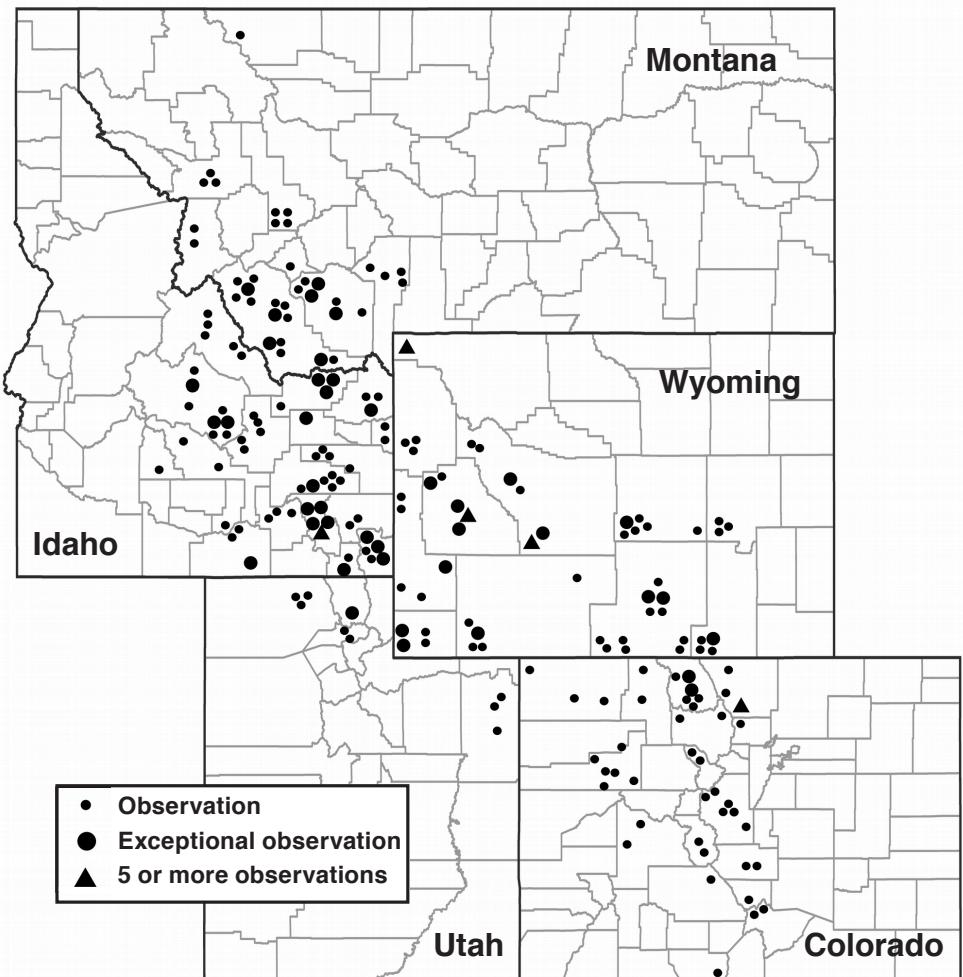

Figure 1. Early historic observations (Tables 1-5) of bison in the Rocky Mountains, USA. Exceptional observations are observer estimates of 1000 or more bison, or descriptions such as "vast herds".

Even before obtaining horses (about 1730) and more so thereafter, Native Americans had effective methods for killing bison (Point nd:121-125; Hornaday 1889:465-484). When large numbers of bison were accessible, both Native- and Euro-Americans often preferred the flesh and hides of cows (Hornaday 1889:465). This selective harvesting would have negatively influenced regeneration of bison numbers.

Native Americans often killed very large numbers of bison. Stuart (Spaulding 1953:116-117) found immense numbers of bison bones in every direction of the upper

Green River Valley, Wyoming, in 1812 and Bonneville observed similar conditions in the same place in 1833 (Irving 1837:95). Clyman (1984:25) observed Crows killing "upwards of a thousand" bison in a day of 1824. Russell (Haines 1965:36) describes one village of Shoshones killing, without guns, "upwards of a thousand cows" in one day of 1835. On the Great Plains, 500 or more Sioux killed 1400 bison in less than a day of 1832 (Catlin in Roe 1951:631) and 100 or more Minatarees and Mandans killed several hundred bison in 15 minutes (Catlin in Hornaday 1889:482). Native Americans often attempted to kill whole herds of bison.

Table 1. Early historic observations of bison in the mountains of Idaho.

In the cited Minataree/Mandan slaughter, every animal of the herd was killed. Using the same hunting technique, the “surround” or “running hunt”, Flatheads (Salish) “usually carried a hunt to the point of extermination.” (Point, nd:141). Literature cited here contains descriptions of pre-hunt ceremonies of Native Americans. Many appear to have believed that providence, more than prudence, determined the continued availability of bison.

These observations of bison slaughter occurred after Native Americans had been greatly and widely diminished by diseases, especially smallpox, which preceded Euro-Americans to the interior of North America. Pandemics eliminating entire local populations and more than half of regional populations have been inferred for smallpox epidemics that included the Rocky Mountain tribes in 1781, 1801 and 1837 (Russell in Haines 1965:86; Thompson in Hopwood 1971:93, 97, 198; Dobyns 1983:15). It is reasonable to assume that much larger populations of Native Americans routinely killed even larger numbers of bison over larger areas prior to arrival of European diseases, affecting where the earliest Euro-American travelers did not find bison.

Unusually deep and persistent snows sometimes greatly depleted local bison herds and may have caused local extirpations, especially in conjunction with continued human harvest. Colonel Dodge reported that thousands of bison starved on the Laramie Plains, Wyoming during an extraordinary winter with deep and crusted snow in 1844-45 (Allen 1877:544). The Plains were never repopulated. Allen (1877:512) noted reports that nearly all the bison in the Salt Lake area, Utah, were destroyed by unusually deep snow about 1837. In 1840, Russell (Haines 1965:121) noted that bison had “long since” been gone from this area.

Williams (2005) used local weather records to conclude that abundant, dense snow, combined with a greater frequency of droughts, had contributed to limiting bison distribution and abundance in the northwest United States during late pre-historic and early historic times. These weather effects

were most notable west of the Rocky Mountains in eastern Washington and Oregon.

Native Americans likely caused local, or even regional, extirpations of bison. In 1806, Sacajawea (Biddle 1962: 510) informed Clark that bison were once numerous in the Gallatin, Jefferson and Beaverhead valleys of Montana, but had disappeared in “but a few years” with concentrated Shoshone hunting. In 1833, near the mouth of the Bitterroot River and the “home base” of Salish, Wyeth noted: “Buffalo have come here and even further but they are killed at once and do not get wonted here.” (Kingston, 1932:168).

## DISCUSSION

During the first half of the 19th century, bison were widely distributed in the intermountain valleys of the Rocky Mountains in the United States. A major regional concentration once occurred in the upper Snake and Salmon River drainages of southeast Idaho, in the upper Green River drainages of southwest Wyoming and over the continental divide along the uppermost tributaries of the Jefferson River in southwest Montana (Fig. 1, Tables 1-3).

Previous authors proposed multiple interacting factors to explain local or regional absence of bison in the northwest United States during early historic time (Van Vuren 1987; Laliberte and Ripple 2003; Lyman 2004; Williams 2005). Three of these references focus on areas west of the Rocky Mountains where bison were absent as Europeans arrived. For this area, authors had no access to recorded observations of Native American/bison interactions. Still, all recognized Native American predation as a factor explaining the early historic absence of bison, as did Meaney and Van Vuren (1993) for southwest Colorado. In contrast, early historic literature from the Rocky Mountains provides abundant descriptions of bison and of Native American predation. These observations provide compelling evidence that human predation was a major, perhaps preponderant, factor limiting bison distribution in the Rocky Mountains. While

other factors varied geographically and temporally, Native American predation was more persistent, mobile and widespread.

Native American ability to extirpate bison or to prevent reestablishment of bison would have been enhanced by:

(1) low bison abundance and productivity in areas with little and inconsistent forage production, due to aridness with frequent droughts and perhaps exacerbated by competitive foraging from wild and Native American horses;

(2) a large Native American population supported by alternative food resources, including salmon, other big game, small game and invertebrates;

(3) periodic major bison declines due to severe winters or prolonged droughts, accentuating the numerical ratio of human predators/prey;

(4a) patchily distributed bison habitat limiting bison mobility as an escape strategy, (4b) isolating source populations for reintroductions, (4c) limiting long term inter-population genetic support and (4d) allowing hunters to predictably locate their prey.

In the reviewed literature, I found no descriptions of epidemic disease in bison before there was contact with Euro-American domestic livestock.

In contrast, the ability of Native Americans to reduce bison numbers would have been limited by distance from permanent villages, especially in areas contested by dangerous enemy tribes (Martin and Szuter 1999; Laliberte and Ripple 2003; Kay 2007). The distance from permanent villages may have contributed to the above noted major abundance of bison in the central Rocky Mountains of the United States.

These interacting factors seem to have characterized much of the land in and especially west of, the Rocky Mountains. No doubt interacting factors varied in time and space. Interacting factors resulted, when Euro-Americans first arrived, in few or no bison west of the Rocky Mountains and, at least periodically, few or none in

some areas within the Rockies. But human predation must have been a preponderant factor in many areas (Urness 1989; Martin and Szuter 1999; Laliberte and Ripple 2003; Kay 2007). After 1824, continued harvesting by both Native- and Euro-Americans rapidly eliminated most bison from the Rocky Mountains. By the 1840's Salish from the Bitterroot Valley, Montana, had to march 24 winter days to find any trace of bison (Point nd:120). In summer, on a more direct route, they traveled 15 days before finding bison (p.166). Eventually, bison remained only as a relict herd in Yellowstone National Park (Skinner, Alcorn, et al. 1951; Meagher et. al 2002).

Early historic records indicate bison were once widespread in non-forested intermountain valleys of the Rocky Mountains. It is less clear if bison persistently used upper mountain elevations in large numbers. Some areas where bison were not recorded by Euro-American explorers likely were lands where bison had been extirpated – for short or long periods - largely by Native Americans. Early historic records provide few geographic limits for restoring the mountain ecotype of bison in the Rocky Mountains.

## ACKNOWLEDGEMENTS

Thanks to Kathryn Qanna Yahu for producing Fig. 1 and to two anonymous reviewers for helpful suggestions. This work was supported in part under 42 U. S. Code, Chapt. 7. Paul Griffen and The Gallatin Wildlife Association defrayed printing costs.
